Data from SDSS

Sloan Digital Sky Survey it's a major astronomical survey that has mapped a large portion of the sky and provided detailed data about billions of celestial objects, including galaxies, stars, and quasars.

Data from SQL (Cataclysmic Variables)

The first thing we do is using the SQL query to obtain several data like basic photometric data of 10,000 CV. The file was download in order to work with pandas.

SQL Search

```
1 -- Search for Cataclysmic Variables and pre-EVs with White Dwarfs and
2 -- very late secondaries, using simple color cuts from Paula Szkody.
3 -- This is a simple query that uses math in the WHERE clause.
4
5 SELECT TOP 100 run,
6 comCol,
7 rerun,
8 field,
9 objID,
10 u, g, r, i, z,
11 ra, dec
12 -- Just get some basic quantities
13 FROM Star -- From all stellar primary detections
14 WHERE u - g < 0.4
15 and g - r < 0.7
16 and r - i > 0.4
17 and i - z > 0.4-- that meet the color criteria
```

Output Format HTML CSV XML JSON VOTable FITS
 MyDB

What we want to do?

With our csv file we have the basic information from this data the filter UGRIZ besides the RA and DEC so with this data we can plot a aintoff projection that is where is located the star in the sky in equatorial coordinates to do this task we support on jupyter notebook.

```
In [1]: import pandas as pd
import numpy as np
import matplotlib.pyplot as plt

In [40]: tv = pd.read_csv("180000v.csv")
tv.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 180000 entries, 0 to 9999
Data columns (total 12 columns):
 #   Column      Non-Null Count  Dtype  
--- 
 0   id          180000 non-null  int64  
 1   catCol     180000 non-null  int64  
 2   rerun     180000 non-null  int64  
 3   flag      180000 non-null  int64  
 4   objID     180000 non-null  int64  
 5   u         180000 non-null  float64 
 6   g         180000 non-null  float64 
 7   r         180000 non-null  float64 
 8   i         180000 non-null  float64 
 9   z         180000 non-null  float64 
 10  ra        180000 non-null  float64 
 11  dec       180000 non-null  float64 
dtypes: float64(11), int64(1)
memory usage: 937.6 kB

Creating a Aintoff Projection

In [52]: plt.style.use('ggplot')
plt.scatter(tv['ra'], tv['dec'], s=10, marker='x', color='red', label='Cataclysmic Variables')
plt.title('Aintoff projection')
plt.xlabel('RA')
plt.ylabel('DEC')
plt.grid(True)
plt.savefig('aintoff.pdf')
plt.show()
```

Figure: Jupyter notebook.

Mean, median, max and min values

With basics statistic using pandas we get this information.

Now we calculate the mean, max, min values for each magnitude

```
In [190]: cv.agg(
    {
        "u": ["min", "max", "median", "mean"],
        "g": ["min", "max", "median", "mean"],
        "r": ["min", "max", "median", "mean"],
        "i": ["min", "max", "median", "mean"],
        "z": ["min", "max", "median", "mean"]
    }
)
```

Out[190]:

	u	g	r	i	z
min	13.516190	14.263300	14.461610	13.547880	11.872420
max	30.377500	31.225310	32.153720	31.183070	29.717600
median	23.686765	24.813360	24.824655	23.532575	21.322145
mean	23.552356	24.668633	24.695767	23.269877	21.468740

Data from APOGEE in SDSS

There is several way to use data in SDSS the way I choose (more complicated as always do) is download the file from DR17 approx 4 GB.

Ways to Access APOGEE Data

Table of Contents This page provides a summary of the available outputs from the different stages of the APOGEE pipelines. These can be obtained via a number of tools.

Quick Links to Data Access

We provide three primary tools to access the APOGEE data: the Science Archive Server (SAS), the Science Archive Webapp (SAW), and the Catalog Archive Server (CAS). File formats are described in the data model and we provide some examples for how to use these resources. However, many users will be satisfied with the [final catalog](#) on the SAS, which gives radial velocities, stellar parameters, and abundances for each star, obtained from the combined spectra. Users should consult the "Using APOGEE Data" pages for further instructions on how to properly use and analyze the APOGEE data.

I want to ...	Tool	Tool Description	APOGEE Quick Links
Download flat files to my computer and write the programs to use the data.	Science Archive Server (SAS)	The SAS houses parameter summary catalogs, spectra, and all intermediate data products in flat files within a directory structure. As described in Supplemental . Analyses there are multiple files in the same folder for different libraries. The default library is synspec with results in the <code>synspec_redux</code> library. (See Caveats for details)	<ul style="list-style-type: none"> • allstar.fits (4.9 Gb, <code>datamodel</code>, link see also this comment) • allstar.txt (1.4 Gb, <code>data mode</code>) • allstar.pkl (2.8 Gb, <code>datamodel</code>)
Use a Web-based GUI interface to select targets or view spectra.	Science Archive Webapp (SAW)	The SAW contains spectra and selected parameters in a user-friendly interactive interface. The SAW is loaded from the <code>synspec_redux</code> library. The CAS contains the information from the summary catalogs in a queryable database structure that can be accessed through the Skyserver or directly via SQL.	<ul style="list-style-type: none"> • Infrared spectrum search • Infrared spectrum View Stars
Query a database with SQL to define a sample.	Catalog Archive Server (CAS)	The CAS is loaded from the <code>synspec_redux</code> library.	<ul style="list-style-type: none"> • HII-type Query Form • Galaxy SQL Query

Figure: APOGEE Data

Keil Diagram

The SDSS offer a basics examples of this using python,

```
In [1]: import numpy as np
from astropy.io import fits
from astropy.table import Table
import matplotlib.pyplot as plt

In [3]: file = './allStar-dr17-synspec_revl.fits'
cv = fits.openfile()

# Refer to the data model to determine that the file has multiple HDUs and we only want the data array.
data = cv[1].data
# Close the remaining HDUs
cv.close()

In [10]: # determine the integer value for the bit 23 in ASPCAPFLAG
badbits = 2**23
# select for ASPCAPFLAG bit 23 not being set and for EXTRATARG to have no bits set
gd = (np.bitwise_and(data['aspcapflag'], badbits) == 0) & (data['extratarg']==0)
# ind = np.where(gd)[0]

In [11]: teff_logg_check = np.logical_and(data["TEFF"] > 0, data["LOGG"] > -18) # this checks for -9999 values
teff_logg_feh_check = np.logical_and(data["FE_H"] > -6, teff_logg_check)

indices = np.where(np.logical_and(gd, teff_logg_feh_check))
good = data[indices] # this only the good data now
```
